Molecular similarity is important for predicting the properties of a complex molecular system, such as a molecule or mixture of compounds. However, the effect of the similarity between molecules on their properties is largely unknown for large arrays of highly conjugated molecules, such as those encountered in organic electronics, because current similarity metrics are limited to comparing molecules at a specific level of conjugation. Here, we use the topological data analysis (TDA) method to quantify three-dimensional (3D) molecular similarity for such a molecular array and to examine its effect on the properties of the molecules. We show that TDA molecular similarity scores between molecules of the same length correlate with the conjugation length and affect the properties of the molecule. We also show that conjugation length differences between molecules in the array are related to the chemical, physical, and electrochemical properties of these molecules. Our findings indicate that the structure and electrical properties of molecules are systematically affected by molecular similarity.Gap junctional permeability and transcriptional regulation of connexin genes. Considerable evidence suggests that the connexin genes (GJCs) of neuronal gap junctions are associated with a variety of specialized functions. To gain insight into the way in which these genes are regulated, we have addressed the question of whether any putative recognition sequences in GJC mRNAs might exhibit a relationship with the transcriptional properties of the GJC genes. We have used an in vitro transcriptional system to examine the regulatory properties of three GJC gene
